We present some statistics on Finnish lichens. The knowledge on taxonomy, distribution and ecology of Finnish lichens is extremely uneven between different lichen groups. At present 1708 lichen species are known from Finland. The number has increased by 20.4 % compared to Vitikainen et al. (1997), even when more than 100 species have been synonymized or proven to be erroneously reported from Finland. Most species are rare in Finland, and 204 species are known from one locality only. The proportion of lichen species known from Finland compared to estimated global number of lichen species is higher than among any other species-rich organism group. This outlines the importance of lichens as a crucial part of the Finnish biodiversity. Data on accepted species described from Finland (n=225) is presented.

## Introduction

Scientific research on Finnish lichens began in the 1850's (Nylander 1852), although some records occur in publications since the 1600's (Brenner 1896). William Nylander (1822–1899), who was born in Oulu, Finland, became the leading lichen taxonomist in the world, describing new species from all over the globe (Ahti 1990, Vitikainen 2001). Nylander also created the lichen floristics in Finland. He encouraged students to lichenological expeditions, arranged funding for them, created channels for publishing the results as well as identified numerous specimens collected by students (Vitikainen 1996). Nylander described a large number of new lichen species from Finland and e.g. contributed to the first published checklist on Finnish lichens (Vitikainen 1996). The latter half of the 1800's was a period of many lichen

expeditions to various parts of Finland (Brenner 1896, Vitikainen 1996, Stenroos et al. 2016). The studies by Edvard A. Vainio (1876–1929) (e.g. Vainio 1881, 1883) were also extremely important for increasing the knowledge on Finnish lichens. In the end of the 1800's the lichen flora of Finland was among the best known in the world.

After Nylander's death the research activity weakened. Nevertheless, new data on Finnish lichens accumulated, just more slowly (see Vitikainen 1996, Stenroos et al. 2016). It was important that Vainio returned to work on Finnish lichens in his old age and published four parts of "Lichenographia Fennica" (Vainio 1921–1934). After Vainio's death Veli Räsänen (1888–1953) became the leading lichenologist in Finland, although Räsänen was a schoolteacher and never had any scientific position at a university (Hakulinen 1956). In addition, many of our bot-

anists had some knowledge on lichens, usually macrolichens, and accumulated biogeographical data on them.

After Räsänen there was again some decline in the studies of Finnish lichen biota. However, the tradition of Finnish lichen taxonomy and biogeography was kept alive by Rainar Hakulinen, Teuvo Ahti and Orvo Vitikainen. Taxonomic studies made by Finnish lichenologists often covered the world, a tradition already started by Nylander. The trade-off of globalization of lichen taxonomy meant less effort on studying Finnish lichens. Globalization was also preferred by scientific funding agencies and possibilities to receive funding for studying Finnish lichen flora were somewhat limited.

Red-listing of species began in the 1980's and resulted also in more interest in the Finnish lichen flora and in the arising of a new generation of lichenologists. For more than a hundred years no checklist of Finnish lichens had been published. This serious shortcoming was corrected by Vitikainen et al. (1997) who published a checklist of Finnish lichens and allied fungi. Biogeographical data on the lichen flora of Finland was presented by Vitikainen (1998).

During the past two decades much new data on Finnish lichens has accumulated and a new checklist was published, as well (see Stenroos et al. 2016). This list was first updated for the new Finnish red-list of lichens (Pykälä et al. 2019) and later for the Finnish Biodiversity Information Facility (FinBIF) (Pykälä et al. 2021) (<https://laji.fi/en/theme/checklist>).

In this paper we present some statistics on the Finnish lichen flora. These figures are based on the recently published updated FinBIF list. We also discuss lichen species described from Finland. We only present data on lichenized fungi. Lichenicolous species and allied fungi are excluded.

## Statistics on Finnish lichen flora

The knowledge on taxonomy, distribution and ecology of Finnish lichens is extremely uneven between different lichen groups. Traditionally, macrolichens have been much better known than crustose lichens. For some lichens probably

50–100 % of their localities are known while for many others the coverage is probably 0–1 % of the localities. We estimate that for over 100 species probably more than half of their localities have been found. Furthermore, ecology and distribution of several hundred species is very poorly understood.

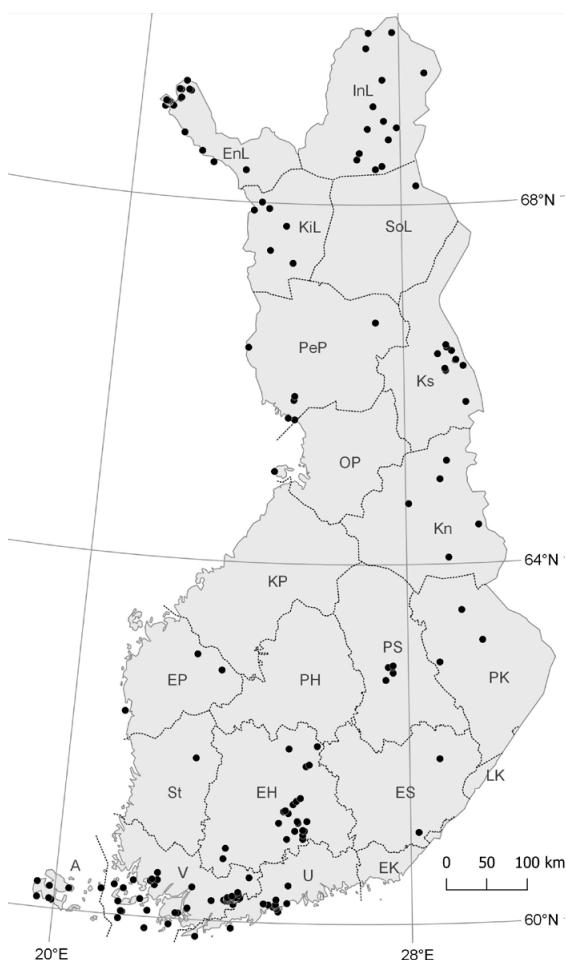

The number of lichen species known from Finland has increased during the recent decades. Vitikainen et al. (1997) listed 1420 lichen species, Stenroos et al. (2016) 1644 species and Pykälä et al. (2019) 1688 species. The current number of lichen species found from Finland is 1708. Thus, the increase is 20.3 % in just over 20 years compared to Vitikainen et al. (1997). More than 100 species have been synonymized or proved to be erroneously reported from Finland after Vitikainen et al. (1997), but c. 380 new species have been added to the checklist.

The most important habitats for lichens are rock outcrops, forests and fells. Altogether 838 species occur mostly on rock outcrops, 547 mostly in forests and 213 mostly on fells. 793 species (46.4 %) grow only or mainly directly on rock surface (epilithic species). 541 species (31.7 %) are epiphytic (including epixylic species). Other species grow on substrates such as soil and moss.

In Finland the south-north gradient is the most prominent gradient as the country is over 1100 kilometers long (Vitikainen 1998). Only 7.9 % of the lichens (135 species) have been found from all biogeographical provinces.

On the contrary, altogether 204 species have been found from one locality only, i.e. 11.9 % of all Finnish lichens. Such a high number of "one locality wonders" suggests that many species have not yet been detected. Species with only one known locality have been mostly found from southern or northernmost part of the country (Figure 1). Highest numbers are from the biogeographical provinces V (48), EnL (38), EH (26) and Ks (19). At commune level most are from the communes Enontekiö (38), Lohja (21), Kuusamo (18), Inari (12) and Parainen (9). 52 of them have been found before the year 1900, and none of these species have been recorded since. 70 species have been first found during the past 20 years.

During the recent decades studies on lichen biota have been focused particularly on habitat

**Fig. 1.** Distribution of lichens found from one locality only in Finland.

types such as calcareous rocks and old-growth forests. This has resulted in a high number of species new to Finland. A particularly high number of lichens new to Finland have been reported from calcareous rocks (Pykälä 2017, 2018 and references in them). Nevertheless, most or all of them are old inhabitants but not recorded before because of high rarity or previous identification problems.

Based on recent studies it is evident that there may be hundreds of lichen species waiting to be found from Finland, from the field or from the herbaria. Most of these species are either difficult to identify or very rare habitat specialists with an extremely small Finnish population. Many semi-cryptic and cryptic species may also occur (Lauhanen et al. 2019a).

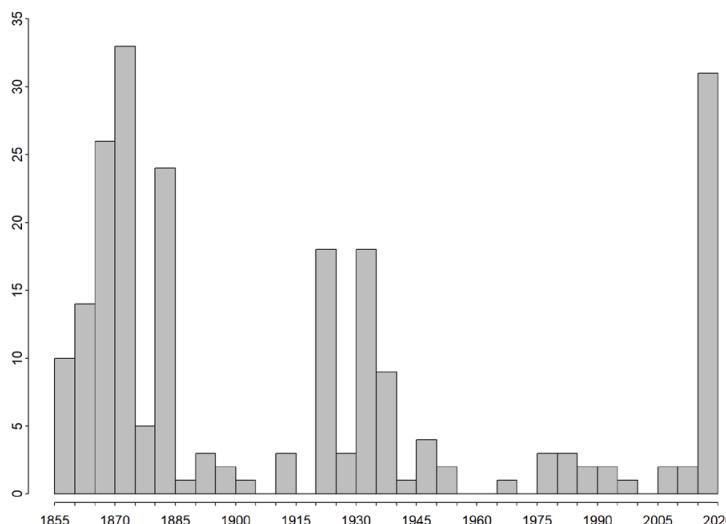

Even if the lichen flora of Finland is well known compared to most other countries of the world, it is less well known compared to birds, vascular plants and bryophytes, for instance. Why so many new lichen species are to be expected? We suggest several explanations. Finland is a relatively large country. The species number of lichens is higher than species number in well-known organism groups. These combined with a low number of lichenologists causes a rather low coverage. In addition, many species are extremely rare habitat specialists that should be intensively searched for in rare habitat types. Globalization of Finnish lichenology started very early. To search for new species has for a long time been unfashionable in science causing difficulties to get any funding. There are very few amateur lichenologists in Finland and the few amateurs search for lichens only besides their major interest organisms. No one has ever searched for new lichen species from Finland as their major long-term duty. The number of cryptic or semi-cryptic species may be high. Thus, in several lichen groups molecular studies may cause an increase in the number of species.

We expect that new species will mainly be found from habitat types already known to be rich in rare lichens. These include calcareous and serpentine rocks, fells, shores, old-growth forests and northern boreal forests. Finland is "a land of thousands of lakes", but lichens growing on shores have largely been neglected.

The proportion of lichen species known from Finland compared to estimated global number of lichen species is 8.2 % (Pykälä 2016). This is a larger proportion than among any other species-rich organism group. This outlines the importance of lichens as a crucial part of the Finnish biodiversity.

## Accepted lichen species described from Finland

Currently, 225 lichen species accepted on the Finnish checklist (i.e. 13.2 % of the Finnish lichen flora) have been originally described from Finland (Table 3). This is a slightly lower number than 15.6 % of the accepted taxa in Vitikainen et al. (1998), which, however, also included li-

◀ Fig. 2. Number of currently accepted species described from Finland during different time periods.

chenicolous and allied fungi. Furthermore, 48 lichen species included in Vitikainen et al. are not accepted anymore as distinct species but are considered as synonyms and thus not counted here. Still, many of the species belong to taxonomically poorly known genera, and many nomenclatural changes are to be expected. Additionally, three species have their neotype from Finland.

More than half of the accepted species having their nomenclatural type from Finland were described between 1858–1898 ( $n=118$ ) (Figure 2). A considerable number of species ( $n=57$ ) were described during the years 1900–1950. Between the years 1951–2000 only fourteen new spe-

cies were described (including infraspecific taxa raised to the species level).

A total of 186 species (82.7 %) have been described by Finnish lichenologists. Even most species described by foreign lichenologists have been originally described as infraspecific taxa by Finnish lichenologists (usually Nylander or Vainio).

More than half of the species were described by W. Nylander and E. Vainio (Table 1). After Vainio V. Räsänen described several species. After Räsänen only few species were described during the latter half of the 2000s century, and most were described by foreign lichenologists (several of them were treated as infraspecific taxa by Nylander and Vainio). Between the years 1960–2000 Finnish lichenologists described only three new species from Finland (Brodo & Vitikainen 1984, Vitikainen 1985, Stenroos 1989) (Figures 3 and 4).

Within the past five years Finnish lichenologists have described 31 new lichen species from Finland (Pykälä & Myllys 2016, Pykälä et al. 2017a, b, 2018, 2018, 2020, Launis & Myllys 2019, Launis et al. 2019a, b). The most important driver for revival of Finnish lichen taxonomy has been the Research Program of Poorly Known and Threatened Forest Species financed by the Ministry of Environment (PUTTE) (2003–2016) (Juslén & Sirkia 2013).

The most important collectors of the type specimens have been E. Vainio and J. P. Norrlin (Table 2). Most of those have been collect-

ed from the biogeographical provinces EH (66), InL (22), V (22), U (19) and Ks (18). The number of accepted species from EH has much declined compared to the value given by Vitikainen (1998) (due to synonymizations) but is still clearly the highest among the biogeographical provinces.

Lichens described from Finland belong to 74 genera. Most of them (205 species, 91.1 %) are crustose lichens. The highest numbers of them are in the genera *Lecidea* (37), *Verrucaria* (30), *Micarea* (14) and *Lecanora* (11).

Dozens of lichens described from Finland have not been reported elsewhere. However, they usually belong to globally poorly known lichen groups, and are likely to occur outside Finland. Nevertheless, several of them may prove to be globally rare species.
